Assignment 1

September 2024

Question 1. Implement the $PA = LDU$ decomposition algorithm discussed in class. Do so yourself (in other words, do not merely use predefined Gaussian elimination code in MatLab or Python). Simplifications: (i) You may assume that the matrix A is square and invertible. (ii) Do not worry about column interchanges, just row interchanges. Demonstrate (in your pdf) that your implementation works properly, on some examples.

Solution We implement a Python class to perform **Gaussian Elimination** on a matrix, decomposing it into permutation (P), lower triangular (L), diagonal (D), and upper triangular (U) matrices.

- **Initialization:** The matrix A is deep-copied and converted to `np.float64`. Matrices P , L , D , and U are initialized.
- **Permutations:** If a pivot is zero, rows are swapped in A and P to maintain numerical stability.
- **Lower Triangularization:** Elements below the diagonal are eliminated via row operations stored in L , followed by adding the identity matrix to finalize L .
- **Diagonal and Upper Matrices:** The diagonal and upper triangular matrices are extracted from the transformed A , with U normalized to have ones on the diagonal.
- **Final Decomposition:** The class returns matrices L , D , U , and P .

```

1 import numpy as np
2 import copy
3
4 class GaussianElimination:
5     """
6     A class to perform Gaussian Elimination on a given matrix A, decomposing
7     it into
8     permutation (P), lower triangular (L), diagonal (D), and upper triangular
9     (U) matrices.
10    """
11
12    def __init__(self, A):
13        """
14        Initialize the GaussianElimination class with matrix A.
15
16        Parameters:
17        -----
18        A : np.ndarray
19            The matrix to be decomposed.
20        """
21        self.A = A.astype(np.float64) # Ensure matrix A is of dtype np.
22                                         float64
23        self.A_ = copy.deepcopy(self.A) # Create a deep copy of A to avoid
24                                         modifying the original matrix
25        self.initialize_matrices()
26
27    def initialize_matrices(self):
28        """
29        Initialize matrices P, L, D, and U based on the dimension of matrix A.
30        """
31        self.dim = self.A.shape[0]
32
33        # Initialize permutation matrix P as an identity matrix
34        self.P = np.eye(self.dim, dtype=np.float64)

```

```

32     # Initialize L as a zero matrix and U, D as zero matrices
33     self.L = np.zeros((self.dim, self.dim), dtype=np.float64)
34     self.D = np.zeros((self.dim, self.dim), dtype=np.float64)

133         Perform Gaussian Elimination to decompose matrix A into L, D, U, and P
134         .
135
136         Returns:
137         -----
138         tuple of np.ndarray
139             A tuple containing the lower triangular matrix (L),
140             diagonal matrix (D), upper triangular matrix (U), and permutation

```

```

136         matrix (P).
137     """
138     self.lower_triangularization()
139     self.extract_diagonal_and_upper()
140     return self.L, self.D, self.U, self.P

```

Listing 1: Gaussian Elimination Class in Python

Here is an example of the class in use for a sample 3×3 matrix A :

```

>>> A = np.array([[1,3,2], [-2,-6,1], [2,5,7]], dtype=np.float64)
>>> GE = GaussianElimination(A)
>>> L,D,U,P = GE.decompose()
>>> print(L)
array([[ 1.,  0.,  0.],
       [ 2.,  1.,  0.],
       [-2.,  0.,  1.]])
>>> print(D)
array([[ 1.,  0.,  0.],
       [ 0., -1.,  0.],
       [ 0.,  0.,  5.]])
>>> print(U)
array([[ 1.,  3.,  2.],
       [-0.,  1., -3.],
       [ 0.,  0.,  1.]])
>>> print(P)
array([[1., 0., 0.],
       [0., 0., 1.],
       [0., 1., 0.]])

```

Listing 2: Gaussian Elimination Class usage for a sample 3×3 matrix A

To reproduce the attached code, run [16-811/Assignment-1/question1.ipynb](#)

Question 2 Compute the $PA = LDU$ decomposition and the SVD decomposition for each of the following matrices:

$$A_1 = \begin{pmatrix} 10 & -10 & 0 \\ 0 & -4 & 2 \\ 2 & 0 & -5 \end{pmatrix} \quad A_2 = \begin{pmatrix} 5 & -5 & 0 & 0 \\ 5 & 5 & 5 & 0 \\ 0 & -1 & 4 & 1 \\ 0 & 4 & -1 & 2 \\ 0 & 0 & 2 & 1 \end{pmatrix} \quad A_3 = \begin{pmatrix} 1 & 1 & 1 \\ 10 & 2 & 9 \\ 8 & 0 & 7 \end{pmatrix}$$

Solution

1. **My apologies, I had copied the matrix last row wrong in my first submission**

First lets compute SVD of A_1

```
>>> import numpy as np
>>> A_1 = np.array([[ 10, -10, 0],
                    [ 0, -4, 2],
                    [ 2, 0, -5]])
>>> U, S, VT = np.linalg.svd(A_1)
>>> U
array([[ -0.97502551,  0.01928246, -0.22125424],
       [-0.19998937, -0.50949125,  0.83691273],
       [-0.09658937,  0.86025976,  0.50062326]])
>>> S
array([14.49778417,  5.94733738,  1.85564877])
>>> VT
array([[ -0.68585887,  0.72771207,  0.00572281],
       [ 0.3217144 ,  0.31024647, -0.89456524],
       [-0.65276141, -0.61170439, -0.44690075]])
```

Now lets compute the LDU decomposition.

Operation	P	L	DU
$r_3 \leftarrow r_3 - 0.2 \cdot r_1$	$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0.2 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 10 & -10 & 0 \\ 0 & -4 & 2 \\ 0 & 2 & -5 \end{pmatrix}$
$r_3 \leftarrow r_3 + 0.5 \cdot r_2$	$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0.2 & -0.5 & 1 \end{pmatrix}$	$\begin{pmatrix} 10 & -10 & 0 \\ 0 & -4 & 2 \\ 0 & 0 & -4 \end{pmatrix}$

Hence we get the following result

$$L = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0.2 & -0.5 & 1 \end{pmatrix} \quad U = \begin{pmatrix} 1 & -1 & 0 \\ 0 & 1 & -0.5 \\ 0 & 0 & 1 \end{pmatrix} \quad D = \begin{pmatrix} 10 & 0 & 0 \\ 0 & -4 & 0 \\ 0 & 0 & -4 \end{pmatrix}$$

And the Permutation matrix P is I_3

2. Lets compute SVD of A_2

```
>>> import numpy as np
>>> A_2 = np.array([[ 5, -5, 0, 0],
                    [ 5,  5, 5, 0],
                    [ 0, -1, 4, 1],
                    [ 0,  4, -1, 2],
                    [ 0,  0, 2, 1]])
>>> U, S, VT = np.linalg.svd(A_2)
>>> U
array([[ 0.1126266 ,  0.86708016,  0.37480574, -0.30750061, -0.0212435 ],
       [-0.93215705,  0.15225202,  0.1626033 ,  0.2846251 ,  0.0212435 ],
       [-0.20196646,  0.2257811 , -0.74973268, -0.31691184, -0.4956816 ],
       [-0.2398716 , -0.41225956,  0.38334628, -0.77085017, -0.17702914],
       [-0.14166742,  0.06368894, -0.35217519, -0.36026217,  0.84973988]])
>>> S
array([9.14492811, 7.79814769, 4.42070712, 2.23976139])
>>> VT
array([[ -0.44807922, -0.65407164, -0.60275097, -0.09003647],
       [ 0.65357327, -0.69875055,  0.28263403, -0.06861233],
       [ 0.60783153,  0.27645026, -0.74051747, -0.07582844],
       [-0.05106685,  0.08667875,  0.09188657, -0.99067443]])
```

Listing 3: SVD of A_2

Now lets compute the LDU decomposition.

Operation	P	L	DU
$r_3 \leftarrow r_3 - r_1$	$\begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 5 & -5 & 0 & 0 \\ 0 & 10 & 5 & 0 \\ 0 & -1 & 4 & 1 \\ 0 & 4 & -1 & 2 \\ 0 & 0 & 2 & 1 \end{pmatrix}$
$r_3 \leftarrow r_3 + 1/10 \cdot r_2$ $r_4 \leftarrow r_4 - 2/5 \cdot r_2$	$\begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 \\ 0 & -0.1 & 1 & 0 & 0 \\ 0 & 2/5 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 5 & -5 & 0 & 0 \\ 0 & 10 & 5 & 0 \\ 0 & 0 & 4.5 & 1 \\ 0 & 0 & -3 & 2 \\ 0 & 0 & 2 & 1 \end{pmatrix}$
$r_4 \leftarrow r_4 + 2/3 \cdot r_3$ $r_5 \leftarrow r_5 - 4/9 \cdot r_3$	$\begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 \\ 0 & -0.1 & 1 & 0 & 0 \\ 0 & 2/5 & -2/3 & 1 & 0 \\ 0 & 0 & 4/9 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 5 & -5 & 0 & 0 \\ 0 & 10 & 5 & 0 \\ 0 & 0 & 4.5 & 1 \\ 0 & 0 & 0 & 8/3 \\ 0 & 0 & 0 & 5/9 \end{pmatrix}$
$r_5 \leftarrow r_5 - 5/24 \cdot r_4$	$\begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 \\ 0 & -0.1 & 1 & 0 & 0 \\ 0 & 2/5 & -2/3 & 1 & 0 \\ 0 & 0 & 4/9 & 5/24 & 1 \end{pmatrix}$	$\begin{pmatrix} 5 & -5 & 0 & 0 \\ 0 & 10 & 5 & 0 \\ 0 & 0 & 4.5 & 1 \\ 0 & 0 & 0 & 8/3 \\ 0 & 0 & 0 & 0 \end{pmatrix}$

Assuming $D_{(5,5)} = 1$ (since the last row is zeros for U), from above we can infer that

$$L = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 & 0 \\ 0 & -1/10 & 1 & 0 & 0 \\ 0 & 2/5 & -2/3 & 1 & 0 \\ 0 & 0 & 4/9 & 5/24 & 1 \end{pmatrix} \quad U = \begin{pmatrix} 1 & -1 & 0 & 0 & 0 \\ 0 & 1 & 1/2 & 0 & 0 \\ 0 & 0 & 1 & 2/9 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix} \quad D = \begin{pmatrix} 5 & 0 & 0 & 0 & 0 \\ 0 & 10 & 0 & 0 & 0 \\ 0 & 0 & 9/2 & 0 & 0 \\ 0 & 0 & 0 & 3/8 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{pmatrix}$$

and P is I_5

3. Lets compute SVD of A_3

```
>>> import numpy as np
>>> A_3 = np.array([[ 1, 1, 1],
                    [ 10, 2, 9],
                    [ 8, 0, 7]])
>>> U, S, VT = np.linalg.svd(A_3)
>>> U
array([[ -0.08686637, -0.57077804, -0.81649658],
       [ -0.78592384, -0.4643889 ,  0.40824829],
       [ -0.6121911 ,  0.67716718, -0.40824829]])
>>> S
array([1.72832333e+01, 1.51322343e+00, 1.63228421e-15])
>>> VT
array([[ -0.74312678, -0.09597244, -0.66223249],
       [  0.1339329 , -0.99096789, -0.0066797 ],
       [  0.65561007,  0.09365858, -0.74926865]])
```

Listing 4: SVD of A_3

Now lets do the LDU decomposition of A_3

Operation	P	L	DU
$r_2 \leftarrow r_2 - 10 \cdot r_1$ $r_3 \leftarrow r_3 - 8 \cdot r_1$	$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 \\ 10 & 1 & 0 \\ 8 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 1 & 1 \\ 0 & -8 & -1 \\ 0 & -8 & -1 \end{pmatrix}$
$r_3 \leftarrow r_3 - r_2$	$\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 0 & 0 \\ 10 & 1 & 0 \\ 8 & 1 & 1 \end{pmatrix}$	$\begin{pmatrix} 1 & 1 & 1 \\ 0 & -8 & -1 \\ 0 & 0 & 0 \end{pmatrix}$

Hence from the above calculation, we get:

$$L = \begin{pmatrix} 1 & 0 & 0 \\ 10 & 1 & 0 \\ 8 & 1 & 1 \end{pmatrix} \quad U = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 1/8 \\ 0 & 0 & 0 \end{pmatrix} \quad D = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -8 & 0 \\ 0 & 0 & 1 \end{pmatrix} \quad P = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

To reproduce the attached code, run [16-811/Assignment-1/question2.ipynb](#)

Question 3 Solve the systems of equations $Ax = b$ for the values of A and b given below. For each system, specify whether the system has zero, one, or many exact solutions. If a system has zero exact solutions, give “the SVD solution” (as defined in class) and explain what this solution means. If a system has a unique exact solution, compute that solution. If a system has more than one exact solution, specify both “the SVD solution” and all solutions, using properties of the SVD decomposition of the matrix A , as discussed in class. Show your work, including verifying that your answers are correct.

$$\text{a)} \quad A = \begin{pmatrix} 10 & -10 & 0 \\ 0 & -4 & 2 \\ 2 & 0 & -5 \end{pmatrix} \quad b = \begin{pmatrix} 10 \\ 2 \\ 13 \end{pmatrix}$$

$$\text{b)} \quad A = \begin{pmatrix} 1 & 1 & 1 \\ 10 & 2 & 9 \\ 8 & 0 & 7 \end{pmatrix} \quad b = \begin{pmatrix} 1 \\ 3 \\ 1 \end{pmatrix}$$

$$\text{c)} \quad A = \begin{pmatrix} 1 & 1 & 1 \\ 10 & 2 & 9 \\ 8 & 0 & 7 \end{pmatrix} \quad b = \begin{pmatrix} 3 \\ 2 \\ 2 \end{pmatrix}$$

Solution:

a) Borrowing from the solution of A_1 from **Question 2**, we use the L, D, U matrix. We use the equation $Ly = b$ where $y = DUx$

$$L = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0.2 & -0.5 & 1 \end{pmatrix} \quad \& \quad Ly = \begin{pmatrix} 10 \\ 2 \\ 13 \end{pmatrix} \implies y = \begin{pmatrix} 10 \\ 2 \\ 12 \end{pmatrix}$$

Since $DUx = y$, $Ux = D^{-1}y$, and since D is a diagonal matrix with non-zero entries we get

$$Ux = D^{-1}y = \begin{pmatrix} 1 \\ -1/2 \\ -3 \end{pmatrix}$$

Now to solve for x we solve from the bottom row and back substitute the values for the upper row equations.

$$\begin{pmatrix} 1 & -1 & 0 \\ 0 & 1 & -0.5 \\ 0 & 0 & 1 \end{pmatrix} x = \begin{pmatrix} 1 \\ -1/2 \\ -3 \end{pmatrix} \implies x = \begin{pmatrix} -1 \\ -2 \\ -3 \end{pmatrix}$$

This system has 1 exact solution since $\mathcal{N}(A) = \phi$

b) we shall use the solution for A_3 from **Question 2**.

$$L = \begin{pmatrix} 1 & 0 & 0 \\ 10 & 1 & 0 \\ 8 & 1 & 1 \end{pmatrix} \quad \& \quad Ly = \begin{pmatrix} 1 \\ 3 \\ 1 \end{pmatrix} \implies y = \begin{pmatrix} 1 \\ -7 \\ 0 \end{pmatrix}$$

Since $DUx = y$, $Ux = D^{-1}y$, and since D is a diagonal matrix with non-zero entries we get

$$Ux = D^{-1}y = \begin{pmatrix} 1 \\ 7/8 \\ 0 \end{pmatrix}$$

Note that we assumed $D_{3,3} = 1$ for convenience, there can be infinitely more solutions. Now we solve for $D^{-1}y = Ux$ by going row wise from bottom.

Since U_1 row is all zeros, we assign any value to x_3 . Let $x_3 = 7$, this will simplify calculations. Hence:

$$\begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 1/8 \\ 0 & 0 & 0 \end{pmatrix} x = \begin{pmatrix} 1 \\ 7/8 \\ 0 \end{pmatrix} \implies x = \begin{pmatrix} -6 \\ 0 \\ 7 \end{pmatrix}$$

Figure 1: Diagrammatic representation of problem 3.b The case of infinite solutions, b resides in the column space of A and the solution is of the form $x_r + tx_n$

Note: this system has infinitely many solutions since $\text{Rank}(A) = 2 < 3 = \text{Dim}(x)$ and all $x = x_r + tx_n$ is a solution of $Ax = b$ where x_n is a sample in the null space of A and x_r resides in the row space. Let us assume $x_3 = t$, where $t \in \mathbb{R}$. Solving the above system gives us:

$$x = \begin{pmatrix} (1 - 7t)/8 \\ (7 - t)/8 \\ t \end{pmatrix}$$

Hence all solutions of the form $x = \begin{pmatrix} 1/8 \\ 7/8 \\ 0 \end{pmatrix} + t \begin{pmatrix} -7/8 \\ -1/8 \\ 1 \end{pmatrix}$ is a solution to the given $Ax = b$.

Now let's compare this to the SVD solution:

```

>>>import numpy as np
>>>A_3 = np.array([[ 1, 1, 1],
                    [ 10, 2, 9],
                    [ 8, 0, 7]])

>>>U, S, VT = np.linalg.svd(A_3)
>>>b=np.array([1,3,1])
>>> S
array([1.72832333e+01, 1.51322343e+00, 1.63228421e-15])
>>>x_ = VT.T @ np.linalg.inv(np.diag(S)) @ U.T @ b
>>>x_
array([[0.01754386],
        [0.85964912],
        [0.12280702]])
>>>VT.T[:, 2]
array([ 0.65561007,  0.09365858, -0.74926865])

```

Listing 5: SVD solution for $Ax = b$ under infite solution case example

As we can see the singular value is 0 (numerical implementation of svd in numpy yields a number of order 10^{-15}) for the last entry, (Ref. Listing 4.) the singular vector corresponding to this (V_3) spans the null space and the component of solution in row space x_r is spanned by V_1 and V_2 . Also we can clearly see that V_3 is just a scaling of $\begin{pmatrix} -7/8 \\ -1/8 \\ 1 \end{pmatrix}$ which we know spans the null space of A and the svd solution is at $t \approx 0.1228$.

c) Along similar lines of previous question,

$$L = \begin{pmatrix} 1 & 0 & 0 \\ 10 & 1 & 0 \\ 8 & 1 & 1 \end{pmatrix} \quad \& \quad Ly = \begin{pmatrix} 3 \\ 2 \\ 2 \end{pmatrix} \implies y = \begin{pmatrix} 3 \\ -28 \\ 6 \end{pmatrix}$$

Since $DUx = y$, $Ux = D^{-1}y$, and since D is a diagonal matrix with non-zero entries we get

$$Ux = \begin{pmatrix} 1 & 1 & 1 \\ 0 & 1 & 1/8 \\ 0 & 0 & 0 \end{pmatrix} x = D^{-1}y = \begin{pmatrix} 3 \\ 7/2 \\ 6 \end{pmatrix}$$

Uh oh!, we have a problem, no matter what x is the last row will always be 0 hence this system has zero exact solution. Lets find the SVD solution using numpy.

$$x = V\Sigma^{-1}U^{\top}b$$

Upon back substitution from the solution of **Question 2** part 3, we get:

```

>>> import numpy as np
>>> A = np.array([[ 1, 1, 1],
                  [ 10, 2, 9],
                  [ 8, 0, 7]])
>>> U, S, VT = np.linalg.svd(A)
>>> b=np.array([[3],[2],[2]])
>>> x_ = VT.T @ np.linalg.pinv(np.diag(S)) @ U.T @ b

```

Figure 2: Representation of problem 3.c The case of inexact solution (no-solution), $x_r = V\Sigma^{-1}U^\top b$

```
>>> x_
array([[0.01754386],
       [0.85964912],
       [0.12280702]])
```

Listing 6: SVD solution for $Ax = b$

This solution corresponds to b' obtained by projecting b onto the columns space of A . $U^\top b$ projects b to the column space and Σ^{-1} rescales the vector along the column space. Upon multiplication with V reprojects it back to the row-space with no component existing in the null space of A

[To reproduce the attached code, run 16-811/Assignment-1/question3.ipynb](#)

Question 4: Suppose that u is an n -dimensional column vector of unit length in \mathbb{R}^n , and let u^\top be its transpose. Then uu^\top is a matrix. Consider the $n \times n$ matrix $A = I - uu^\top$.

- (a) Describe the action of the matrix A geometrically.
- (b) Give the eigenvalues of A .
- (c) Describe the null space of A .
- (d) What is A^2 ?

Solution:

a) $Av = v - \begin{pmatrix} u_1 \cdot u^\top \\ \dots \\ u_n \cdot u^\top \end{pmatrix} v = v - (u^\top v) \cdot u$. Hence geometrically this matrix operation eliminates all components of a vector along the direction of u resulting in only the component of v orthogonal to u since $(Av)^\top u = 0$. uv .

Figure 3: The effect of applying the transformation A on a vector v

b) $Au = 0 \cdot u$ implies u is an eigenvector with eigenvalue 0. Which also implies u spans the null space of A . Since we are in \mathbb{R}^n , it would have a basis on n orthogonal vectors (eigenvectors). since u is one of them and the rest are orthogonal to it, all v s.t. $v \perp u$ satisfies $Av = v$ implying an eigen value of 1. Hence there are $n - 1$ eigenvalue 1 and the last eigen value is 0.

c) From b), the null space is the space of all vectors aligned with vector u , i.e. of the form tu

d) $A^2 = A^\top A = (I - (uu^\top))^\top (I - uu^\top) = (I - uu^\top)(I - uu^\top) = I - 2uu^\top + uu^\top uu^\top = I - uu^\top$, Hence this is the same matrix transformation again.

Question 5: The following problem arises in a large number of robotics and vision problems: Suppose p_1, \dots, p_n are the 3D coordinates of n points located on a rigid body in three-space. Suppose further that q_1, \dots, q_n are the 3D coordinates of these same points after the body has been translated and rotated by some unknown amount. Derive an algorithm in which Singular Value Decomposition (SVD) plays a central role for inferring the body's translation and rotation. (You may assume that the coordinate values are precise, not noisy, but see the comment and caution below.)

Show (in your PDF) that your algorithm works correctly by running it on some examples.

Comment: This problem requires some thought. There are different approaches. Although you can find a solution on the web or in a vision textbook, try to solve the problem yourself before looking at any such sources. Spend some time on the problem. It is good practice to develop your analytic skills. Feel free to discuss among yourselves. (As always, cite any sources, including discussions with others.)

Requirement: Your algorithm should make use of all the information available. True, in principle, you only need three pairs of points — but if you use more points, your solution will be more robust, something that might come in handy some day when you need to do this for real with noisy data.

Caution: A common mistake is to derive an algorithm that finds the best affine transformation, rather than the best rigid body transformation. Even though you may assume precise coordinate values, imagine how your algorithm would behave with noise. Your algorithm should still produce a rigid body transformation.

Hint: Suppose for a moment that both sets of points have the origin as centroid. Assemble all the points $\{p_i\}$ into a matrix P and all the points $\{q_i\}$ into another matrix Q . Now think about the relationship between P and Q . You may wish to find a rigid body transformation that minimizes the sum of squared distances between the points $\{q_i\}$ and the result of applying the rigid body transformation to the points $\{p_i\}$.

You may find the following facts useful (assuming the dimensions are sensible):

$$\|x\|^2 = x^\top x, \quad x^\top R^\top y = \text{Tr}(Rxy^\top).$$

[Here x and y are column vectors (e.g., 3D vectors) and R is a matrix (e.g., a 3×3 rotation matrix). The superscript T means transpose, so $x^\top x$ is a number and xy^\top is a matrix. Also, Tr is the trace operator that adds up the diagonal elements of its square matrix argument.]

You will have more complicated expressions for x and y , involving the points $\{p_i\}$ and $\{q_i\}$.

Solution : Let us solve the Translation and rotation independently. The translation required to go from $P \rightarrow Q$ can be found by:

$$\begin{aligned} \arg \min_T \sum_{i=1..n} \|p_i + T - q_i\|^2 &= \arg \min_T \sum_{i=1..n} (p_i + T - q_i)^\top (p_i + T - q_i) \\ &= \arg \min_T \sum_{i=1..n} (p_i^\top p_i + q_i^\top q_i) + nT^\top T + 2T^\top \sum_{i=1..n} (p_i - q_i) \end{aligned}$$

Since $\sum_{i=1..n} (p_i^\top p_i + q_i^\top q_i)$ is not a function of T we can get rid of them from the objective.

$$\begin{aligned} &\arg \min_T nT^\top T + 2T^\top \left(\sum_{i=1..n} (p_i - q_i) \right) \\ &= \arg \min_T nT^\top T + 2T^\top \left(\sum_{i=1..n} (p_i - q_i) \right) \end{aligned}$$

Upon factorizing we get the quadratic equation :

$$\arg \min_T T^\top (nT + 2(\sum_{i=1..n} (p_i - q_i)))$$

We know this is a upward facing parabola and the minima is achieved at the mid point of the two roots, hence $T = \sum_{i=1}^n (p_i - q_i)/n$.

For ease of computation of the required rotation R we shall assume $\tilde{q}_i = q_i - T$ so that their centroid align to compute the rotation. We know that $Rp_i = \tilde{q}_i$ where R is a rotation matrix. We know that since R is a rotation only, there is no scaling along the axis. R minimizes the square distance error post-rotation, hence

$$\begin{aligned} & \arg \min_R \sum_i (Rp_i - \tilde{q}_i)^2 \\ &= \arg \min_R \sum_i p_i^\top R^\top Rp_i - \tilde{q}_i^\top \tilde{q}_i - 2\tilde{q}_i^\top Rp_i \\ &= \arg \min_R \sum_i p_i^\top R^\top Rp_i - \tilde{q}_i^\top \tilde{q}_i - 2\tilde{q}_i^\top Rp_i \end{aligned}$$

Since $R^\top R = I$ and $p_i^\top p_i, \tilde{q}_i^\top \tilde{q}_i$ are not a function of R

$$\arg \min_R \sum_i -2\tilde{q}_i^\top Rp_i = \arg \max_R \sum_i \tilde{q}_i^\top Rp_i$$

The above objective can be rewritten as the trace of $\tilde{Q}^\top RP$ where \tilde{Q} and P are the matrices whose columns are the vectors \tilde{q}_i and p_i respectively. By using the properties of the trace $\text{Tr}()$ of a matrix, the objective can be rewritten as:

$$= \arg \max_R \text{Tr}(\tilde{Q}^\top RP) = \arg \max_R \text{Tr}(RP\tilde{Q}^\top)$$

Upon performing the SVD of $P\tilde{Q}^\top = USV^\top$ and using $\text{Tr}(AB) = \text{Tr}(BA)$ we get

$$\arg \max_R \text{Tr}(RUSV^\top) = \arg \max_R \text{Tr}(SV^\top RU)$$

Let's assume $G = V^\top RU$, which is an orthogonal matrix since it is the product of 3 orthogonal matrices. The trace of SM is $\sum_i^n (S_{i,i}M_{i,i})$ which only maximizes when $M_{ii} = 1$, but since it is also orthogonal, $M = I$, hence

$$M = I \implies V^\top RU = I \implies R = VU^\top$$

Algorithm 1 Rigid Body Translation and Rotation via SVD

- 1: **Input:** 3D point sets $\{p_i\}, \{q_i\}$ for $i = 1, \dots, n$
 - 2: **Output:** Translation T , Rotation R
 - 3: Compute translation $T \leftarrow \frac{1}{n} \sum_{i=1}^n (q_i - p_i)$
 - 4: Align centroids: $\tilde{q}_i \leftarrow q_i - \frac{1}{n} \sum_{i=1}^n q_i, \tilde{p}_i \leftarrow p_i - \frac{1}{n} \sum_{i=1}^n p_i$
 - 5: Compute rotation by solving $\arg \max_R \text{Tr}(R \tilde{P} \tilde{Q}^\top)$
 - 6: Perform SVD: $USV^\top \leftarrow \tilde{P} \tilde{Q}^\top$
 - 7: Set $R \leftarrow VU^\top$
 - 8: **Return:** T, R
-

The following Python class calculates the translation and rotation matrices needed for rigid body motion between two 3D point sets using Singular Value Decomposition (SVD).

```
1 import numpy as np
2
3 class RigidBodyTransformation:
4     def __init__(self, P, Q):
5         """
6         Initialize with two 3D point sets P and Q.
7
8         Parameters:
9         P (numpy.ndarray): 3D point set before transformation (n x 3)
10        Q (numpy.ndarray): 3D point set after transformation (n x 3)
11        """
12        self.P = P
13        self.Q = Q
14        self.centroid_P = np.mean(self.P, axis=0)
15        self.centroid_Q = np.mean(self.Q, axis=0)
16        self.T = None # Translation vector
17        self.R = None # Rotation matrix
18
19    def compute_translation(self):
20        """
21        Compute the translation vector T as the difference between centroids.
22        """
23        self.T = self.centroid_Q - self.centroid_P
24
25    def compute_rotation(self):
26        """
27        Compute the rotation matrix R using SVD.
28        """
29        # Step 2: Align centroids
30        P_centered = self.P - np.mean(self.P, axis=0)
31        Q_centered = self.Q - np.mean(self.Q, axis=0)
32
33        # Step 3: Compute rotation matrix
34        H = P_centered.T @ Q_centered # Covariance matrix
35        U, S, Vt = np.linalg.svd(H) # SVD decomposition
36        self.R = Vt.T @ U.T
37
38
39    def infer_transformation(self):
40        """
41        Perform the full inference of translation and rotation.
```

```

42         """
43         self.compute_translation()
44         self.compute_rotation()
45         return self.T, self.R
46
47     def apply_transformation(self, P):
48         """
49         Apply the computed transformation to a given 3D point set P.
50
51         Parameters:
52         P (numpy.ndarray): 3D point set to transform (n x 3)
53
54         Returns:
55         numpy.ndarray: Transformed point set.
56         """
57         if self.T is None or self.R is None:
58             raise ValueError("Transformation not yet computed. Call
59                               infer_transformation first.")
60
61         # center it according to the centroid of P, then rotate it, then
62         # translate it
63         return ((P-self.centroid_P) @ self.R.T) + self.centroid_P + self.T

```
